

Functions with Results

Look at this code:

```
def add_score(first, second):  
    total = first + second  
  
    return total  
  
print("Score:", add_score(7, 5))
```

Use the code above to help you. After completing each challenge below, run your program to test that it works correctly. Save each completed challenge program in a new file.

Programming Challenges

Challenge 1

Use the same function with two different pairs of scores. Before each run, work out the total you expect, then compare it with the returned value.

Challenge 2

Capture the returned total in a variable named `score` and display a labelled result on the next line. The function itself should not print the answer.

Challenge 3

A small shop needs a `total_cost(price, delivery)` function. Return the combined cost, store it, and display it with a clear label. For `total_cost(12, 3)`, the result should be 15.
