

Functions with 2D Data

Look at this code:

```
def find_members(records, target):
    for record in records:
        if record[0] == target:
            return record[1]
    return -1
clubs = [["art", 12], ["chess", 18], ["code", 15]]
for record in clubs:
    print(record[0])
name = input("Club to find: ")
members = find_members(clubs, name)
print("Search result:", members)
```

Use the code above to help you. After completing each challenge below, run your program to test that it works correctly. Save each completed challenge program in a new file.

Programming Challenges

Challenge 1

Use `find_members()` to find the number of members in "art" and "code". Display "Art: 12" and "Code: 15" after the three club names.

Challenge 2

Add a function `total_members(records)` that loops through the rows, maintains a running total, and returns it. Display the labelled total; the supplied data must produce 45.

Challenge 3

Store ["ari", 7], ["bao", 9] and ["cleo", 8] in [results]. Write `show_records(records)` to display every name and score. Write `find_score(records, target)` to `return` the matching score or -1. Write `highest_score(records)` to `return` the highest score. In the main program, call all three functions. Test "Bao"; display "Score: 9" and "Highest score: 9". Test "Mina"; display "Name not found." and "Highest score: 9".
