

Functions with 2D Data

Look at this code:

```
def show_names(records):
    for record in records:
        print(record[0])
def find_members(records, target):
    for record in records:
        if record[0] == target:
            return record[1]
    return -1
clubs = [["art", 12], ["chess", 18], ["code", 15]]
show_names(clubs)
name = input("Club to find: ").lower()
members = find_members(clubs, name)
print("Search result:", members)
```

Use the code above to help you. After completing each challenge below, run your program to test that it works correctly. Save each completed challenge program in a new file.

Programming Challenges

Challenge 1

Change the search target to code. The final labelled result must be 15 while all three club names still display first.

Challenge 2

Add a function `total_members(records)` that loops through the rows, maintains a running total, and returns it. Display the labelled total; the supplied data must produce 45.

Challenge 3

Build a small results manager using `[name, score]` rows and three functions: display every record, search by lower-case name, and return the highest score. The main program must call all three and show a clear not-found message for a missing name.
