

Functions with 2D Data

Look at this code:

```
def find_members(records, target):
    for record in records:
        if record[0] == target:
            return record[1]
    return -1
clubs = [["art", 12], ["chess", 18], ["code", 15]]
for record in clubs:
    print(record[0])
name = input("Club to find: ")
members = find_members(clubs, name)
print("Search result:", members)
```

Use the code above to help you. After completing each challenge below, run your program to test that it works correctly. Save each completed challenge program in a new file.

Programming Challenges

Challenge 1

Change the example so it makes two fixed searches instead of asking for a club. Call `find_members()` with `clubs` and "art", then with `clubs` and "code". Display the results as "Art: 12" and "Code: 15" after the club names.

Challenge 2

Change the example so it adds up the members instead of searching. Write `total_members(records)`, which uses a `for` loop to add each row's count to `total`, then `return total`. Display the club names, then "Total members: 45".

Challenge 3

Create a 2D `list` called `results` with rows ["ari", 7], ["bao", 9] and ["cleo", 8]. Write `show_records(records)` to display each name and score, and `find_score(records, target)` to `return` a matching score, or `return -1`. Call `show_records()`, ask for a name, then display "Score:" with the result, or "Name not found." for -1.
